### Metallic bonding

Metals LOSE ELECTRONS to form POSITIVE IONS

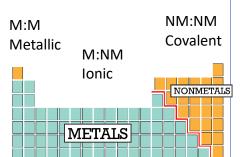

GIANT structures of atoms in a REGULAR pattern

Delocalised electrons are free to move.

What is a metallic bond?

Sharing delocalised electrons - STRONG metallic bonds.

## Which type of bonding is it?

## Ionic bonding

Metals LOSE ELECTRONS to form **POSITIVE IONS** Non-metals GAIN ELECTRONS to form NEGATIVE IONS

Electrons transferred from metal to non-metal

Ions have electronic structure of a noble gas

What is an ionic bond? STRONG electrostatic force of attraction between oppositely charged ions

How do we quickly work out the charges on ions?

Group	Electrons in outer shell	Charge on ion
1	1	1+
2	2	2+
6	6	2-
7	7	1-

## C3 Structure and Bonding

### Covalent **Bonding**

Two non-metals will SHARE pairs of electrons

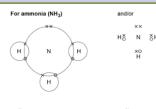

STRONG bond formed.

#### **Small molecules**

A small group of atoms sharing electrons

**Giant Structures** 

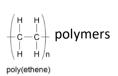

Many atoms

#### Limitations of these models

Model	Limitations
Dot and cross	Looks like electrons aren't identical Electrons look like they are in fixed positions
н-N-H Displayed formula	Doesn't show true shape of the molecule
Ball and stick	Can attempt to show 3D shape but doesn't show electrons

# Properties of Metallic Substances

Metals have high melting and boiling points **because...** 

...they are giant structures of atoms with strong metallic bonding

Can be bent or shaped **because...** 

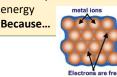

...atoms are arranged in **LAYERS** which can **SLIDE** over each other

Alloys are harder than pure metals because...

Alloys are a mixture of two or more elements, at least one of which is a metal ....the layers are

**DISTORTED** so can't slide over each other

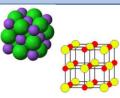

Metals are good conductors of electricity and thermal energy metal ions

...the **electrons** are free to move and carry thermal energy and charge

## Properties of lonic Substances

lonic compounds have high melting and boiling points **because...** 

...they are giant structures of atoms (giant ionic lattice) with strong electrostatic forces of attraction in ALL DIRECTIONS between oppositely charged ions.

A large amount of **energy** is needed to break the many strong bonds.

Only conduct electricity when melted or dissolved in water because...

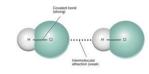

...the **ions are free** to move and so charge can flow.

## C3 Structure and Bonding

#### **Small molecules**

Small molecules have relatively low melting and boiling points because...

...intermolecular forces are overcome on melting and boiling and these are weak forces.

The bigger the size of the molecule the higher the melting and boiling point because...

...intermolecular forces increase with the size of the molecules.

Don't conduct electricity **because...** 

...the molecules have **no overall electric charge**.

## Properties of Covalent substances

Polymers are solids at room temperature because...

...intermolecular forces increase with the size of the molecules and polymer molecules are **very large**.

Giant covalent compounds have high melting and boiling points because...

...all of the atoms linked by **strong covalent bonds**.

Graphene is strong, light

and an excellent

because...

because...

conductor of thermal

energy and electricity

Diamond is very hard, has a very high melting and boiling point and doesn't conduct electricity because...

...each carbon is bonded to 4 other carbons by strong covalent bonds. There are no free electrons.

Graphite is very hard, has a very high melting and boiling point and does conduct electricity

because... Strong Bonds in the layer

..it is a single layer of graphite so lent has free electrons.

Fullerenes (e.g. carbon nanotubes) are extremely strong and are excellent conductors of thermal energy and electricity

...each carbon is bonded to **3** other carbons by **strong covalent bonds**. It forms **layers** of **hexagonal rings** with no covalent bonds between layers. There are **free electrons**.

... they have strong covalent bonds and free electrons.
